Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid (Art. 99(1) European patent convention).

Description

FIELD OF THE INVENTION

5 The present invention relates to disposable absorbent articles such as diapers, incontinence briefs and incontinence pads. Such articles comprise components which render them especially effective for absorbing discharged body fluids while at the same time preventing or reducing diaper rash and preventing or controlling odor.

10 BACKGROUND OF THE INVENTION

Diaper rash is a common form of irritation and inflammation of those parts of an infant's body normally covered by a diaper. This condition is also referred to as diaper dermatitis, napkin dermatitis, napkin rash, and nappy rash. While certainly more common in infants, this condition is not, in fact, limited to infants. Any individual who suffers from incontinence to the extent that the use of absorbent articles is required may develop this condition. This ranges from newborns, to the elderly, to critically ill or nonambulatory individuals.

It is generally accepted that true "diaper rash" or "diaper dermatitis" is a condition which is, in its most simple stages, a contact irritant dermatitis. The irritation of simple diaper rash results from extended contact of the skin with urine, or feces, or both. Diapers are worn to catch and hold the body waste, but generally hold the waste in direct contact with the skin until changed, i.e., in occluded fashion for long periods of time. The same is true for an incontinence pad, or incontinence brief. However, while it is known that the body waste "causes" diaper rash, the precise component or components of the urine or feces which are responsible for the resulting irritation of the skin have not been conclusively identified. The most commonly accepted list of factors linked to diaper rash includes ammonia, bacteria, the products of bacterial action, urine pH, *Candida albicans*, and moisture. These are generally cited in the art as being the most likely candidates for agents or conditions which produce or aggravate diaper rash.

As discussed in Berg and Stewart, U.S. Patent 4,685,909, Issued August 11, 1987, a primary cause of diaper rash appears to be a particular set of conditions which arises as a result of prolonged contact of skin with mixtures of feces and urine. Activity of proteolytic and lipolytic fecal enzymes, as well as fecal bacteria, present in such a mixture is believed to be a major factor in producing skin irritation. Urine in contact with enzymes and bacteria from feces can also result in production of ammonia which raises skin pH (and causes odor). This rise in skin pH, for example to levels of 6.0 and above, in turn increases that fecal proteolytic and lipolytic enzymatic activity which produces diaper rash. Urine itself can also contribute to diaper rash by adding moisture to the diaper environment. Water, and particularly water in the form of urine, is especially effective at diminishing the barrier property of skin, thereby enhancing the susceptibility of skin to fecal enzyme irritation. However, when skin pH is kept between 3.0 and 5.5, the skin's barrier properties can be maintained. The foregoing diaper rash model suggests that effective diaper rash control can be achieved by maintaining skin pH well within the acidic range to inhibit irritation-producing enzymatic activity while simultaneously maintaining the diaper environment as dry as possible.

One factor in preventing a rise in skin pH to within the alkaline range involves the maintenance of aqueous fluids, e.g., urine, feces and/or mixtures thereof, discharged into and held within the diaper or incontinence article at an acidic pH. This can be accomplished by taking steps to inhibit ammonia formation in the article, by donating protons to the discharged liquids held within the absorbent article or by a combination of these methods. A number of prior art references, in fact, teach the addition of various acidic pH control or "ammonia-absorbing" agents to absorbent articles such as diapers, and agents of this type do tend to inhibit the rise of pH of aqueous fluids in the diaper. References with such disclosures include, for example, Alonso et al, U.S. Patent 4,382,919, Issued May 10, 1983; Blaney, U.S. Patent 3,964,486, Issued June 22, 1976; Bryce, U.S. Patent 3,707,148, Issued December 26, 1972; and Jones, Sr., U.S. Patent 3,794,034, Issued February 26, 1974.

One type of pH control agent or "buffering agent" frequently found in disposable absorbent articles comprises the slightly cross-linked polymeric gelling agents or "supersorbers" which serve to imbibe liquids discharged into the article. These materials frequently contain at least some unneutralized carboxylic acid or sulfonic acid groups in the polymer chain, and these acid groups can donate protons to fluid within the article. Polymeric gelling agents of this type are thus especially desirable components of the absorbent articles since they not only improve the absorbency characteristics of the article but they also provide at least some acid buffering capacity with respect to fluids in the article.

Whether the acidic pH control agent is of the polymeric gelling agent type or not, pH control agents alone will frequently not be able to provide sufficient buffering capacity to prevent a rise in the pH of urine or other discharged fluids within the absorbent article. This is because the amount of urine discharged into the typical absorbent article is often greater than the buffering capacity of the pH control agent can handle.

5 Another factor which works against the action of an acidic buffering agent in inhibiting urine pH rise involves the presence of inorganic contaminants in the urine. Human urine, for example, frequently will contain bicarbonate salts which, after the urine is discharged, can decompose to produce CO₂. CO₂ dissipation from voided urine in turn tends to promote a rise in urine pH which can overcome whatever acid buffering capacity might be provided by the acidic pH control agent.

10 The foregoing considerations involving diaper rash, ammonia production and the importance of pH control of fluids within the absorbent article indicate that there is a continuing need to identify absorbent articles and components thereof which are especially effective for preventing the occurrence of conditions that favor the development of diaper rash and the production of odor-causing materials. Accordingly, it is an object of the present invention to provide disposable absorbent articles which are especially effective for
15 reducing or preventing diaper rash and ammonia production. It is a further object of the invention herein to provide such absorbent articles which utilize readily available, non-toxic, non-irritating materials to provide the desired rash and odor combatting effectiveness. It is a further object of the present invention to provide absorbent articles of this type which can be prepared by relatively straightforward, conventional absorbent article production methods.

20 SUMMARY OF THE INVENTION

The present invention is directed to disposable absorbent articles useful for absorbing urine and feces discharged by incontinent individuals. Such articles also tend to reduce or prevent diaper rash and
25 production of ammonia. According to the present invention there is provided a disposable absorbent article useful for absorbing urine and feces discharged by incontinent individuals while reducing or preventing diaper rash, said absorbent article comprising:

- (A) a liquid impervious backing sheet;
- (B) a relatively hydrophobic, liquid pervious topsheet;
- 30 (C) an absorbent core positioned between said backing sheet and said topsheet, said absorbent core comprising hydrophilic fiber material and
- (D) a pH control system,

wherein the absorbent article being characterized in that the pH control system consisting of:
35 (i) an acidic buffering agent formed by particles of a partially neutralised slightly cross-linked polymeric gelling agent having a degree of neutralisation of no more than 90%, and a gel volume of at least 20 grams of synthetic urine per gram of gelling agent; and
(ii) an antimicrobial agent selected from quaternary nitrogen-based compounds and bisguanide compounds, said antimicrobial agent being combined with said absorbent core and present in or on
40 said core in a concentration of from 0.02% to 2.0% by weight of the core, with said buffering agent and said antimicrobial agent being present within said pH control system in a weight ratio of from 3:1 to 2000:1, with said pH control system being present in said absorbent article in an amount which is effective to maintain the pH of *Proteus vulgaris*-contaminated, bicarbonate-containing urine discharged into said article at a value below 7.5.

45 BRIEF DESCRIPTION OF THE DRAWING

The drawing submitted herewith represents a cutaway view of a disposable diaper which is a preferred configuration for the absorbent articles herein.

50 DETAILED DESCRIPTION OF THE INVENTION

The absorbent articles of the present invention can be manufactured in the configuration of wearable disposable absorbent products which are capable of absorbing significant quantities of aqueous body waste fluids such as urine and feces. Thus such articles, for example, may be prepared in the form of disposable
55 diapers, adult incontinence briefs, adult incontinence pads and the like.

The absorbent articles herein will generally comprise at least three basic structural elements. One such element is a liquid impervious backing sheet. On top of this backing sheet is placed a second structural element which is an absorbent core. This absorbent core may itself comprise one or more distinct layers or

zones. On top of this absorbent core is placed a third structural element which is a relatively hydrophobic, liquid pervious topsheet. The topsheet is the element of the article which is placed next to the skin of the wearer. In one embodiment, described more fully hereinafter, the articles herein will also include as a fourth structural element a flexible substrate, e.g., an insert, containing one or more components of the pH control system. Such an insert can be placed on top of the topsheet next to the skin of the wearer.

Especially preferred absorbent articles of this invention are disposable diapers. Articles in the form of disposable diapers are fully described in Duncan and Baker, U.S. Patent Re 26,151, Issued January 31, 1967; Duncan, U.S. Patent 3,592,194, Issued July 13, 1971; Duncan and Gellert, U.S. Patent 3,489,148, Issued January 13, 1970; and Buell, U.S. Patent 3,860,003, Issued January 14, 1975.

A preferred disposable diaper for the purpose of this invention comprises an absorbent core; a topsheet superposed or co-extensive with one face of the core, and a liquid impervious backsheet superposed or co-extensive with the face of the core opposite the face covered by the topsheet. Both the backsheet and the topsheet most preferably have a width greater than that of the core thereby providing side marginal portions of the backsheet and topsheet which extend beyond the core. Frequently the backsheet and the topsheet will be fused together in these side marginal portions. The diaper is preferably constructed in an hourglass configuration.

The backsheet of the articles herein can be constructed, for example, from a thin, plastic film of polyethylene, polypropylene, or other flexible moisture impeding material which is substantially water impervious. Polyethylene, having an embossed caliper of approximately 0.038mm (1.5 mils), is especially preferred.

The topsheet of the article herein can be made in part or completely of synthetic fibers or films comprising such materials as polyester, polyolefin, rayon, or the like, or of natural fibers such as cotton. In nonwoven topsheets, the fibers are typically bound together by a thermal binding procedure or by a polymeric binder such as polyacrylate. This sheet is substantially porous and permits a fluid to readily pass therethrough into the underlying absorbent core.

Another suitable type of topsheet comprises the topsheets formed from liquid impervious polymeric material such as polyolefins. Such topsheets can have tapered capillaries of certain diameter and taper positioned in the topsheet to permit flow of discharged fluid through the topsheet into the underlying absorbent core of the article.

All of the topsheets used in the articles of the present invention are relatively hydrophobic in comparison with the absorbent core of said articles. Topsheet construction is generally disclosed in Davidson, U.S. Patent 2,905,176, Issued September 22, 1959; Del Guercio, U.S. Patent 3,063,452, Issued November 13, 1962; Holliday, U.S. Patent 3,113,570, Issued December 10, 1963, and Thompson, U.S. Patent 3,929,135; Issued December 30, 1975.

Preferred topsheets are constructed from polyester, rayon, rayon/polyester blends, polyethylene or polypropylene.

The absorbent core, which may itself comprise one or more separate and/or distinct zones, e.g., layers, is positioned between the backing sheet and the topsheet to form the absorbent articles herein. Such an absorbent core essentially comprises a web or batt of hydrophilic fiber material. For purposes of the present invention, a fiber is "hydrophilic" if water or aqueous body fluid readily spreads on or over the surface of the fiber (without regard to whether or not the fiber actually imbibes fluid or forms a gel). The hydrophilic fibers which are employed in the absorbent core will generally have an average diameter which ranges from 1 - 200 micrometers. More preferably, the average diameter of these hydrophilic fibers will range from 10 to 100 micrometers. Substantially all of the hydrophilic fibers incorporated into the structures herein preferably have a fiber length of at least 1 mm.

The type of hydrophilic fiber material is not critical for use in the absorbent cores of the articles of the present invention. Any type of hydrophilic fiber which is suitable for use in conventional absorbent products is also suitable for use in the absorbent articles herein. Examples of hydrophilic fiber material include cellulose, modified cellulose, rayon, polyesters such as polyethylene terephthalate (DACRON), and the like. Suitable hydrophilic fibers also include hydrophobic fibers which have been hydrophilized with a hydrophilizing agent. Such fibers include surfactant-treated or silica-treated thermoplastic fibers derived, for example, from polyolefins such as polyethylene or polypropylene, polyacrylics, polyamides, polystyrenes, polyurethanes and the like.

For reasons of availability and cost, cellulosic fibers are generally preferred for use herein as the hydrophilic fiber component of the absorbent core. Most preferred are wood pulp fibers. However, other cellulosic fiber materials may also be used. Such other hydrophilic fiber materials include the stiffened, curled, cellulosic fibers which can be produced by cross-linking cellulose fibers with C₂₋₈ dialdehyde cross-linking agents. Fibers of this type can be defined in terms of their dry fiber and wet fiber twist counts (at

least 4.5 twist nodes per millimeter dry and at least 3.0 twist nodes per millimeter wet) and by their fluid retention characteristics (average isopropyl alcohol retention value of less than 30%; average water retention value of from 28% to 50%). Stiffened, curled cellulosic fibers of this type are described in greater detail in European Patent Application No. 87305614.7, Filed June 24, 1987 in the name of The Procter & Gamble Company.

Depending upon whether or not other materials are present in the absorbent core, hydrophilic fiber material will generally comprise from about 45% to 100% by weight of the absorbent core. Since components other than hydrophilic fiber will generally be present in the absorbent cores of the articles herein, hydrophilic fiber material will preferably comprise from - 60% to 95% by weight of the core, more preferably from 70% to 90% by weight of the core.

The essential element of the absorbent articles herein which serves to combat diaper rash and odor comprises a pH control system. Such a pH control system may be either structural or nonstructural in character. This pH control system itself essentially comprises two components, i.e., an acidic buffering agent and a non-toxic, non-irritating, non-volatile antimicrobial agent. As described more fully hereinafter, such a pH control system serves to forestall the pH rise which would normally occur within discharged body fluids held within the disposable absorbent article. This effect in turn is believed to be responsible for preventing or minimizing the development of diaper rash and ammonia odor.

The acidic buffering agent component of the pH control system comprises the hydrogel-forming, polyacid-based absorbent gelling agents. These gelling agents, in addition to acting as buffering agents, also act as absorbents or gellants for aqueous fluids discharged into the absorbent core. Hydrogel-forming polymeric buffering agents of this type are those which, upon contact with fluids (i.e., liquids) such as water or body fluids, imbibe such fluids and thereby form hydrogels. In this manner, fluid discharged into the absorbent structures herein can be acquired and held by such absorbent gelling agent buffers. These absorbent gelling agent buffers used herein will comprise substantially water-insoluble, slightly cross-linked, partially neutralized, hydrogel-forming polymer materials prepared from polymerizable, unsaturated, acid-containing monomers. In such materials, the polymeric component formed from unsaturated, acid-containing monomers may comprise the entire gelling agent or may be grafted on to other types of polymer moieties such as starch or cellulose. Acrylic acid grafted starch materials are of this latter type and are especially preferred for use herein. Thus the preferred absorbent gelling agent buffers include hydrolyzed acrylonitrile grafted starch, acrylic acid grafted starch, polyacrylates, maleic anhydride-based copolymers and combinations thereof. Especially preferred absorbent gelling buffers are the polyacrylates and acrylic acid grafted starch.

Whatever the nature of the basic polymer components of the preferred hydrogel-forming absorbent buffering agents, such materials will in general be slightly cross-linked. Cross-linking serves to render these preferred hydrogel-forming absorbent buffering agents substantially water-insoluble, and cross-linking also in part determines the gel volume and extractable polymer characteristics of the hydrogels formed therefrom. Suitable cross-linking agents are well known in the art and include, for example, (1) compounds having at least two polymerizable double bonds; (2) compounds having at least one polymerizable double bond and at least one functional group reactive with the acid-containing monomer material; (3) compounds having at least two functional groups reactive with the acid-containing monomer material; and (4) polyvalent metal compounds which can form ionic cross-linkages. Cross-linking agents of the foregoing types are described in greater detail in Masuda et al; U.S. Patent 4,076,663; Issued February 28, 1978.

Preferred cross-linking agents are the di- or polyesters of unsaturated mono- or polycarboxylic acids with polyols, the bisacrylamides and the di- or triallyl amines. Especially preferred cross-linking agents are N,N'-methylenebisacrylamide, trimethylol propane triacrylate and triallyl amine. The cross-linking agent will generally comprise from 0.001 mole percent to 5 mole percent of the preferred hydrogel-forming polymeric gelling agent buffer materials. More preferably, the cross-linking agent will comprise from 0.01 mole percent to 3 mole percent of the absorbent buffering agents used herein.

The slightly cross-linked, hydrogel-forming absorbent buffering agents are employed in their partially neutralized form. For the purposes of this invention, such materials are considered partially neutralized when at least 25 mole percent, and preferably at least 50 mole percent of monomers used to form the polymer are acid group-containing monomers which have been neutralized with a salt-forming cation. Suitable salt-forming cations include alkali metal, ammonium, substituted ammonium and amines. This percentage of the total monomers utilized which are neutralized acid group-containing monomers is referred to herein as the "degree of neutralization." As indicated hereinbefore, such materials must not have a degree of neutralization greater than 90% if they are to be useful as acidic buffering agents in the articles herein.

The preferred absorbent gelling agent buffers used in the pH control system of the articles herein are those which have a relatively high capacity for imbibing fluids encountered in the absorbent articles. This capacity can be quantified by referencing the "gel volume" of the absorbent gelling agent buffers which are preferably used in the present invention. For purposes of this invention, gel volume can be defined in terms of the amount of synthetic urine absorbed by any given absorbent gelling agent buffer and is specified as grams of synthetic urine per gram of gelling agent.

Gel volume in synthetic urine can be determined by forming a suspension of 0.1-0.2 parts of dried absorbent gelling agent buffer to be tested with 20 parts of this synthetic urine. This suspension is maintained at ambient temperature under gentle stirring for 1 hour so that swelling equilibrium is attained. Using a procedure described in greater detail hereinafter in the Test Methods section, the gel volume of the absorbent gelling agent buffer in grams of synthetic urine per gram of absorbent gelling agent buffer is then calculated from the weight fraction of the gelling agent in the suspension and the ratio of the liquid volume excluded from the formed hydrogel to the total volume of the suspension. The preferred absorbent gelling agent buffers useful in this invention will have a gel volume of from 20 to 70 grams, more preferably from 30 to 60 grams, of synthetic urine per gram of absorbent gelling agent buffer.

Another feature of the preferred absorbent gelling agent buffers which are useful as one component of the pH control system of the articles herein relates to the level of extractable polymer material present in such hydrogel-forming buffers. Extractable polymer levels can be determined by contacting a sample of preferred hydrogel-forming absorbent gelling agent buffer material with a synthetic urine solution for the substantial period of time (e.g., at least 16 hours) which is needed to reach extraction equilibrium, by then filtering the formed hydrogel from the supernatant liquid, and finally by then determining the polymer content of the filtrate. The particular procedure used to determine extractable polymer content of the preferred absorbent gelling agent buffers herein is set forth in Brandt, Goldman and Inglin; U.S. Patent 4,654,039; Issued March 31, 1987. The absorbent gelling agent buffer materials which are especially useful in the absorbent articles herein are those which have an equilibrium extractables content in synthetic urine of no more than about 17%, preferably no more than about 10% by weight of the absorbent gelling agent buffer.

The absorbent gelling agent buffers hereinbefore described can be incorporated into the cores of the absorbent articles of the present invention in the form of discrete particles. Such absorbent gelling agent buffer particles can be of any desired shape, e.g., spherical or semi-spherical, cubic, rod-like polyhedral, etc. Shapes having a large greatest dimension/smallest dimension ratio, like needles and flakes are also contemplated for use herein. Agglomerates of absorbent gelling agent buffer particles may also be used.

The size of the absorbent gelling agent buffer particles may vary over a wide range. For reasons of industrial hygiene, average particle sizes smaller than 30 micrometers are less desirable. Particles having a smallest dimension larger than 2 mm may also cause a feeling of grittiness in the absorbent article, which is undesirable from a consumer aesthetics standpoint. Furthermore, rate of fluid absorption can be affected by particle size. Larger particles have very much reduced rates of absorption. Preferred for use herein are absorbent gelling agent buffer particles substantially all of which have a particle size of from 30 micrometers to 2 mm. "Particle Size" as used herein means the weighted average of the smallest dimension of the individual particles.

The amount of polymeric gelling agent buffer particles articles herein will depend upon the degree of buffering and absorbent capacity desired and the nature of the antimicrobial agent in the pH control system as discussed more fully hereinafter. If, however, the absorbent gelling agent buffer is to effectively function as an absorbent or well as a buffer, the absorbent gelling agent buffer particles must be present in the absorbent core in particular concentrations. Thus, absorbent gelling agent buffers will preferably comprise from 2% to 50% by weight of the absorbent core, more preferably from 5% to 20% by weight of the absorbent core.

When absorbent gelling agent buffer particles are to be used in the hydrophilic fiber-containing cores of the absorbent articles herein, such cores can be prepared by any process or technique which provides a web comprising a combination of the fibers and the gelling agent buffer particles. For example, web cores can be formed by air-laying a substantially dry mixture of hydrophilic fibers and absorbent gelling agent buffer particles and, if desired or necessary, by densifying the resulting web. Such a procedure is described more fully in Weisman and Goldman; U.S. Patent 4,610,678; Issued September 9, 1986.

As indicated in this U.S. Patent 4,610,678, the air-laid webs formed by such a procedure will preferably comprise substantially unbonded fibers and will preferably have a moisture content of 10% or less.

The density of the absorbent cores which comprise webs of hydrophilic fibers and absorbent gelling agent buffer particles can be of some importance in determining the absorbent properties of the cores and of the absorbent articles in which such cores are employed. The density of such absorbent cores herein will

preferably be in the range of from 0.06 to 0.3 g/cm³, and more preferably within the range of from 0.09 to 0.22 g/cm³. Typically the basis weight of the absorbent cores herein can range from 0.02 to 0.12 g/cm².

Density values for cores of this type are calculated from basis weight and caliper. Caliper is measured under a confining pressure of 0.137 psi (0.94 kPa). Density and basis weight values include the weight of the hydrogel-forming buffer particles. Density of the cores herein need not be uniform throughout the core. Within the density ranges hereinbefore set forth, the cores can contain regions or zones of relatively higher or relatively lower density.

The second essential component of the pH control system utilized in the absorbent articles herein is an antimicrobial agent. An antimicrobial agent, for purposes of this invention, can be any substance or moiety which either destroys microorganisms (e.g., bacteria) or inhibits, suppresses or prevents their growth and/or metabolism when such microorganisms are present in the articles herein. The antimicrobial agents useful in the absorbent articles of the present invention are substances of this type which are also substantially non-toxic, non-irritating and non-volatile as more particularly hereinafter defined.

It is believed that the antimicrobial agent functions in the pH control systems herein by preventing or reducing microbial growth or metabolism in the discharged liquid held within the absorbent articles herein. Such reduced microbial growth or metabolism prevents or reduces microbial action on discharged urine and/or feces in the article to thereby prevent or minimize ammonia production. This is important since excessive ammonia production, especially in the presence of bicarbonate-containing urine, will cause a rise in the skin pH in the diaper/brief area, even in the presence of a buffering agent. The antimicrobial agent component of the pH control system thus works in combination with the acidic buffering agent to maintain the pH of discharged fluid in the absorbent article below 7.5. This, in turn, facilitates the maintenance of an acidic skin pH in the diaper/brief area. Since ammonia production is minimized, odor problems associated with the presence of ammonia can also be alleviated.

Antimicrobial agents include those useful in the pH control system herein are generally well known materials. For example, an extensive disclosure of various types of antimicrobial agents is found in Kirk-Othmer; Encyclopedia of Chemical Technology, Third Edition, Vol. 7, (1979) pp 793-832. Of all the antimicrobial agents disclosed in this reference, those which are substantially non-toxic, non-irritating and non-volatile are suitable for use in the pH control system of the present invention.

Since absorbent articles containing the pH control system components are to be maintained in contact with the wearer's skin, the antimicrobial agent component of the pH control system, like the acidic buffer, must be one which is substantially non-toxic and non-irritating. An antimicrobial agent is substantially non-toxic and non-irritating if, during the period the absorbent articles are worn, the antimicrobial agent by virtue of its chemical and physical characteristics causes substantially no toxic substance to be released into the body of the wearer and no significant amount of irritation or reddening of the wearer's skin.

Antimicrobial agents used in the pH control system of the absorbent articles herein must also be substantially non-volatile. Non-volatile antimicrobial agents are those which will not evaporate or sublime out of the absorbent article to any significant degree during the time period between manufacture and use of the article. Thus, antimicrobial agents in solid form or antimicrobial agents which leave solid residues are preferred for incorporation into the absorbent articles herein. On the other hand, antimicrobial agents in liquid form, such as alcoholic antimicrobials, should not be utilized.

Of the various types of antimicrobial agents known in the art, those specified for use herein are the quaternary nitrogen-based antimicrobials and the bis-biguanides. These two types of antimicrobial agents have a combination of desirable properties (e.g., relatively high antimicrobial activity, relatively low toxicity and irritation potential and acceptable physical characteristics) which make them especially suitable for use in the articles of this invention.

The antimicrobial agents which contain a single quaternary nitrogen moiety include the hydrocarbyl substituted ammonium compounds as well as those compounds wherein the quaternary nitrogen is part of a heterocyclic ring, e.g., pyridinium compounds. Representative examples of suitable quaternary nitrogen-based antimicrobial agents include methylbenzethonium chloride, benzalkonium chloride, dodecyltrimethyl ammonium bromide, tetradecyltrimethyl ammonium bromide and hexadecyltrimethyl ammonium bromide. Heterocyclic quaternary nitrogen-based antimicrobial agents include dodecylpyridinium chloride, tetradecylpyridinium chloride, cetylpyridinium chloride (CPC), tetradecyl-4-ethylpyridinium chloride and tetradecyl-4-methylpyridinium chloride.

Other preferred antimicrobial agents are the bis-biguanides. The bis-biguanides are also known antimicrobial agents. They are described in detail, for example, in Rose et al, U.S. Patent 2,684,924, Issued July 27, 1954; Senior et al, U.S. Patent 2,990,425, Issued June 27, 1961; Burtwell et al, U.S. Patent 2,830,006, Issued April 8, 1958; and Burtwell et al, U.S. Patent 2,863,019, Issued December 9, 1958.

The most preferred bis-biguanides are 1,6-bis(4-chlorophenyl)diguanidohexane, known as chlorhexidine, and its water-soluble salts. Especially preferred are the hydrochloride, acetate and gluconate salts of chlorhexidine.

The antimicrobial agent component, is present in the pH control system of the absorbent articles herein in an amount such that the weight ratio of acidic buffering agent to antimicrobial agent ranges from 3:1 to 2000:1. More preferably, the weight ratio of buffering agent to antimicrobial agent within the pH control system will range from 25:1 to 1000:1. As can be seen from these ratios, the amounts of buffering agent and antimicrobial agent relative to each other can vary widely. This is because of the broad range of antimicrobial activity encountered in the various types of antimicrobial agents which can be used in the pH control systems herein.

The overall concentration of the pH control system in the absorbent articles of the present invention will depend upon the relative buffering capacity of the particular buffering agent selected and the relative strength of the particular antimicrobial agent employed. However, an appropriate concentration of the pH control system can be determined by referencing the effectiveness of the system in combating the ammonia-producing effects of one particular microorganism, Proteus vulgaris. Proteus vulgaris is a microorganism which is representative of species which are commonly found in the intestinal tract and which are capable of degrading urea in urine to ammonia. Furthermore, Proteus vulgaris is a microorganism which is relatively resistant to antimicrobial agents and which is thus in general relatively difficult to control using antimicrobial agents.

The two-component pH control system should be utilized in the articles herein in an amount which is effective to maintain the pH of Proteus vulgaris-contaminated, bicarbonate-containing urine discharged into the article at a value below 7.5. More preferably, the pH control system should maintain the pH of Proteus vulgaris-contaminated, bicarbonate-containing urine discharged into the article at a value below 6.5. A standard procedure for determining the effectiveness of the pH control system in maintaining pH within these limits is set forth hereinafter in the examples.

When the pH control system is found entirely within the absorbent core of the article, it is generally possible to specify the concentration of the pH control system by quantifying the amount of absorbent gelling agent buffer and the amount of the antimicrobial agent in the core. Thus preferably pH control systems of this type are utilized in an amount such that the absorbent gelling agent buffer comprises from 2% to 50% by weight of the core and the antimicrobial agent comprises from 0.02% to 2.0% by weight of the core. More preferably in articles of this type, the absorbent gelling agent buffer will comprise from 5% to 20% by weight of the absorbent core, and the antimicrobial agent will comprise from 0.05% to 1.0% by weight of the core.

The antimicrobial agent component of the pH control system incorporated into the absorbent articles herein may or may not comprise a distinct, discernible structural element of the articles. Thus, for example, the antimicrobial agent may be utilized in discrete particulate (including fiber) form such that this component is readily discernible within the article. Alternatively, the antimicrobial agent component may be intimately associated, for example, by coating, by impregnating, or by actually chemically bonding, with one of the other structural elements (eg., the topsheet, the absorbent core or an insert layer) of the article.

The acidic buffering agent component of the pH control system is incorporated into the absorbent core of the absorbent articles by intimately admixing such gelling agent particles with the hydrophilic fiber material which forms the core.

In another embodiment of the articles here, the antimicrobial agent component of the pH control system is impregnated into the hydrophilic fiber material forming the absorbent core. This can be accomplished either before or after the absorbent core is formed. In embodiments wherein the absorbent core is formed by airlaying the hydrophilic fibers to form a web, for example, in the manner described in U.S. Patent 4,610,678, the antimicrobial agent can actually be incorporated, e.g., impregnated, into the drylap used to form the hydrophilic fibers.

In yet another embodiment, the antimicrobial agent component of the pH control system may be incorporated on or in a water-insoluble, flexible substrate which is positioned on top of the topsheet of the absorbent article next to the wearer's skin. This substrate may be provided as an insert or liner which may or may not be affixed to the article topsheet. The water-insoluble flexible substrate in this insert or liner embodiment can comprise any suitable material which will act as a carrier for such components. Thus the substrate can be in the form of cloth, a nonwoven substrate, eg., paper, a film, or a sponge structure. Such substrates can be constructed of, for example, cellulose fiber, polyolefins, polyesters, rayon, and the like.

The antimicrobial agent can be combined with the flexible insert or liner substrate in any manner which provides the component(s) in releasable form. Thus the pH antimicrobial agent, in either solid or liquid form, can be admixed with the substrate material as the substrate is being formed. Alternatively, the antimicrobial

agent can be added to, impregnated in or sprayed on the insert or liner substrate after the substrate is formed.

The insert or liner substrate will generally not be large enough to cover the entire area of the article topsheet. Preferably the insert or liner will cover only from 20% to 90% of the top surface area of the topsheet on which the insert substrate is placed. Thickness of the insert or liner substrate can vary widely depending upon the substrate type and the amount and type of antimicrobial agent that it carries. Insert or liner substrates useful herein will generally range in thickness from 0.2 to 1.5 cm.

The insert or liner substrate can be actually secured to the topsheet of the absorbent article in order to ensure that the insert or liner is properly positioned once the absorbent article is applied to the wearer. Thus the insert or liner may be glued to the topsheet or otherwise affixed using two-sided adhesive tape or similar attaching means. Alternatively the insert or liner substrate may simply be positioned on the absorbent article topsheet at the time the article is applied and not affixed to the topsheet in any way.

An embodiment of the disposable absorbent articles herein in the form of a disposable diaper is shown in the drawing. The hourglass-shaped diaper structure of the drawing comprises a liquid impervious backing sheet 101. Positioned on the top of the backing sheet 101 is an hourglass-shaped absorbent core 102 containing the pH control system of the present invention. This core contains hydrophilic fiber material 103 such as wood pulp fiber, impregnated with an antimicrobial agent such as cetylpyridinium chloride. Also distributed throughout the absorbent core 102 are particles 104 of absorbent gelling agent buffer. These particles serve both as a buffering agent and as a gelling agent which imbibes fluid reaching the diaper core. Positioned on top of the hourglass-shaped absorbent core 102 is liquid pervious topsheet 105.

TEST METHODS

In describing the preferred embodiments of the present invention, characteristics of absorbent gelling agent buffer particles are specified. Where reported, these gel volume characteristics can be determined using the following test method:

Gel volume in terms of grams of synthetic urine absorbed per gram of absorbent gelling agent buffer is determined by swelling the polymer samples in several aliquots of synthetic urine. The amount of such synthetic urine actually absorbed by the absorbent gelling agent buffer is determined by a procedure which involves use of a synthetic urine solution containing Blue Dextran so that optical absorbance measurements can be used to calculate the amount of synthetic urine that is not taken up by the hydrogel which forms.

a) Blue Dextran Solution Preparation

A 0.03% Blue Dextran (BD) solution is prepared by dissolving 0.3 parts of Blue Dextran (Sigma D-5751) in 1000 parts of Synthetic Urine (SU) solution. Synthetic Urine is 15.0 parts of 1% TRITON X-100, 60.0 parts of NaCl, 1.8 parts of $\text{CaCl}_2 \cdot 2\text{H}_2\text{O}$, and 3.6 parts of $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$, diluted to 6000 parts with distilled H_2O . The resulting solution has an absorbance of about 0.25 at its absorbance maximum of 617 nm.

b) Hydrogel Equilibration

Aliquots of the hydrogel-forming absorbent gelling agent buffer to be tested are swelled in (i) 20 parts of Synthetic Urine (SU) solution and (ii) 20 parts of Blue Dextran (BD) solution. The suspension in the Blue Dextran (BD) solution is prepared in duplicate. For most hydrogels, 0.1 - 0.25 parts of hydrogel-forming dried powder is required to give a sufficiently high spectrophotometer reading relative to the Blue Dextran reference solution. One hour of equilibration at ambient temperature under gentle stir-bar stirring is usually sufficient for swelling equilibrium to be attained. After equilibration, a 3 ml aliquot of supernatant is separated from each gel suspension by decantation followed by centrifugation.

c) Gel Volume Determination

The optical absorbency (ABS) of each supernatant is determined spectrophotometrically with an accuracy of 0.001 absorbance units. The Synthetic Urine solution is used as an ABS = 0.0 reference. The absorbency of the supernatant from the synthetic urine suspension without Blue Dextran should not exceed 0.01 A; higher values indicate scattering from residual hydrogel gel particles or residual additives, and further centrifugation is necessary. The absorbency of the Blue Dextran supernatants should exceed the absorbency of the Blue Dextran reference solution by at least 0.1 absorbance units. Absorbency values below this range indicate the need to adjust the amount of polymeric gelling agent used to prepare the gel suspension.

d) Gel Volume Calculation

The Gel Volume in synthetic urine of the absorbent gelling agent buffer in gms/gm is calculated from (i) the weight fraction of the absorbent gelling agent buffer in the gel suspension and (ii) the ratio of the excluded volume to the total volume of the suspension. Since Blue Dextran is excluded from the

hydrogel due to its high molecular weight, this ratio is related to the measured absorbencies. The following equation is used to calculate the gel volume:

$$\text{Gel Volume} = \left[\frac{(\text{gms BD Solution})}{(\text{gms absorbent gelling agent}^*)} \right] \times \left[\frac{1 - (\text{ABS BD solution})}{(\text{ABS BD supernatant} - \text{ABS SU supernatant})} \right]$$

* Corrected to a dry weight basis

The various embodiments of the absorbent articles hereinbefore described as illustrated by the following examples:

EXAMPLE I

An adult incontinence product is prepared with an air-laid absorbent core of southern softwood/pine fibers (Foley fluff) having distributed therein buffer particles of partially neutralized, sodium polyacrylate gelling agent buffer and having impregnated therein cetylpyridinium chloride (CPC) antimicrobial agent. This air-laid core is prepared by disintegrating CPC-impregnated drylap and airlaying the resulting fibers into an absorbent web.

A. Drylap Preparation

To impregnate the drylap, a standard roll of Foley drylap, cut to the desired weight, is placed in a cylindrical tank containing a mixture of CPC and ethyl alcohol (15.3 mg of CPC per ml of EtOH). The CPC/EtOH solution is allowed to wick into the drylap completely. The soaked drylap is then placed in an oven equipped with an air blower. The air blower is run (no oven heat) until all of the alcohol is evaporated. Target concentration of CPC in the drylap is 10 mg of CPC per gram of drylap (1% by weight).

B. Absorbent Core Preparation

Two separate layers of fibrous webs are used to form the absorbent core of the adult incontinence product of this example. A primary, generally hourglass-shaped layer containing little or no gelling agent is used as an overlay to a smaller generally rectangular insert layer containing approximately 30% by weight of the insert of absorbent gelling agent buffer particles. Both the overlay and the insert are made from the CPC-impregnated drylap hereinbefore described.

For both layers, the CPC-impregnated drylap is fed into a millhouse disintegrator for disintegration and fluffing. For the overlay layer, this fluffed material is air-conveyed through a disperser where it is further purified and dispersed prior to laydown on a 40 x 40 copper wire screen. For the insert layer, 70% neutralized sodium polyacrylate gelling agent buffer particles (gel volume = 40 g/g) are dispersed into an air stream and laid down simultaneously with the fluff drylap on the copper screen in the manner generally described in U.S. Patent 4,610,678.

Both the overlay and the gelling agent-containing insert webs are conducted to a calender roll where they are compressed to the desired density (0.048 g/cm³ for the overlay; 0.047 g/cm³ for the insert). The basis weight target for the overlay is 0.031 g/cm² (0.20 g/in²). The target basis weight for the insert is 0.026 g/cm² (0.17 g/in²).

C. Article Preparation

The two types of webs hereinbefore described are fashioned into a multi-layer adult incontinence product. Such a product comprises a formed film topsheet prepared from polyethylene with a plurality of tapered capillaries in the general manner described in U.S. Patent 3,929,135. The hourglass-shaped primary absorbent layer is positioned beneath the topsheet and the rectangular insert layer is positioned beneath the primary absorbent layer in a manner such that the insert is generally positioned toward the front of the incontinence product. A fluid impervious polyethylene backing sheet is positioned underneath the two airfelt

layers which form the absorbent core.

Both the topsheet and the backsheet have a width substantially greater than that of the absorbent core, and the topsheet and backsheet are fused to each other in the side marginal portions of these elements which extend beyond the core. Elastic material is positioned within these extended fused side marginal portions in the manner described in Buell; U.S. Patent 3,860,003; Issued January 14, 1975.

Such an incontinence product, which contains both CPC and an absorbent gelling agent buffer within the absorbent core, is especially effective at maintaining the pH of Proteus vulgaris-contaminated urine discharged into the device at a value below about 7.5.

10 EXAMPLE II

CPC-containing drylap, prepared in the manner described in Example I, is also used to prepare cores for disposable diaper products. As with the adult incontinence product of Example I, the diapers herein also have a dual layer absorbent core. These cores are made in the same general manner set forth in Example I for the incontinence product cores.

The primary layer of the absorbent core is an hourglass-shaped web of CPC-impregnated Foley fluff containing about 15% by weight of the same 70% neutralized sodium polyacrylate gelling agent buffer used in Example I. The hourglass-shaped layer has a basis weight of approximately 0.0315 g/cm² (0.203 g/in²).

The insert layer of the absorbent core also comprises CPC-impregnated Foley fluff containing about 15% by weight of the gelling agent buffer particles. The insert has a basis weight of approximately 0.039 g/cm² (0.252 g/in²).

A dual core disposable diaper is prepared utilizing a thermally bonded polypropylene topsheet, the hourglass-shaped primary core hereinbefore described positioned below the topsheet, the oval insert hereinbefore described positioned underneath the hourglass-shaped core and a fluid-impervious polyethylene backing sheet underneath the hourglass and insert core layers. The oval insert is positioned toward the front half of the diaper such that the front one-third section of the diaper core has a higher basis weight than does the back two-thirds of the diaper core. Such a CPC and gelling agent-containing diaper is especially effective at maintaining pH of Proteus vulgaris-contaminated urine discharged into the diaper at a value below about 7.5.

30 EXAMPLE III

A model has been developed to test the ability of Foley fluff absorbent cores containing various types of pH control systems to maintain Proteus vulgaris-contaminated urine within the alkaline range over a 24-hour period. The materials and test methods used in such a model are described as follows:

Bicarbonate-Rich Urine

Urine samples from two human donors are passed through a sterilizing filter (Nalgene, 0.45μ pore). The pH is then adjusted to 6.2 (if necessary 1N HCl or 1N NaOH), and nitrogen gas bubbled into the urine for 30 minutes (room temperature). The pH is measured again and adjusted to 6.2 if necessary. Bubbling of nitrogen gas through the urine sample is repeated and pH is readjusted to 6.2 until the pH virtually stabilizes (i.e., pH 6.15-6.25). Usually three nitrogen bubbleings are sufficient. This pH 6.2 bicarbonate-depleted urine is passed through a sterilizing filter again. Then 1.5 mg of sodium bicarbonate is added per ml of urine. The pH is adjusted to 6.8 (if necessary). These bicarbonate-rich urine samples are used immediately, with care taken to minimize CO₂ loss (minimum headspace, 4° C temperature).

Fluff-Containing Antimicrobials

Foley drylap is treated with either an aqueous or ethanolic solution of the antimicrobial agent to be tested. After drying (18 hours, room temperature in a hood), the drylap is converted to fluff (airfelt) in a Waring blender and stored in a plastic container until used. Test swatches weighing 1 gram are prepared from this airfelt by forming the airfelt into a cohesive patch. Some test swatches contain 15% by weight of particles of a 70% neutralized sodium polyacrylic gelling agent (gel volume = 40 g/g) which serves as an acidic buffering agent.

Proteus vulgaris Inoculum

The ammoniogenic bacterium Proteus vulgaris is grown in trypticase soy broth (TSB) medium containing no dextrose. Cloudy suspensions of Proteus vulgaris (18-hour cultures) are measured for optical density at 420 nm). If necessary, these bacterial suspensions are diluted with TSB to obtain an optical density between 1.0 and 1.7, and are then used as the bacterial inoculum (1:100) in the testing.

Testing System

A test swatch of desired fluff is placed in an 8 oz. wide mouth glass jar. Bicarbonate-rich urine of an initial measured pH of 6.8 and containing 1 ml of Proteus vulgaris suspension per 100 ml is added to the test swatch (4X loading), then tamped down with a glass piston to a uniform wad. The jar lid is secured, followed by a 24-hour incubation at 37°C. The pH (24-hour) is then measured using a surface electrode and recorded. These initial and 24-hour pH values are tabulated for each system and are set forth in Table I.

The Table I data indicate that various combinations of antimicrobial agent and acidic buffer in the form of partially-neutralized, polymeric gelling agent are effective in maintaining the pH of *Proteus vulgaris*-contaminated, bicarbonate-rich urine in the generally acid range, provided such combinations are used above a particular minimum concentration. In the absence of one component or the other in these pH control systems, pH of the urine does rise well into the alkaline range after 24 hours.

EXAMPLE IV

A disposable diaper is prepared according to the teachings of U.S. Reissue Patent No. 26,151. Such a diaper consists of a thin backsheet of polyethylene attached to a pad of absorbent airfelt formed by
 5 disintegrating drylap impregnated with 1% by weight of cetylpyridinium chloride (CPC). Impregnated drylap of this type is prepared in the manner described in Example I.

The combined backsheet and CPC airfelt wadding is overlaid with a compliant, porous, hydrophobic, nonwoven fabric web diaper liner (topsheet) having a weight of approximately 17 grams per square yard (20.3 g/m²). Such a topsheet comprises 0.22 Tex rayon and contains 28 percent by weight of a
 10 thermoplastic binder. The combined laminated structure is approximately 15 X 18 inches (38.1 X 45.7 cm) and is folded into a box pleat configuration by means of a multiplicity of longitudinal folds.

A hot melt of adipic acid is prepared by heating adipic acid above 152°C. The molten adipic acid is applied to the absorbent airfelt wadding prior to its assemblage in the above diaper by metering the acid melt with a positive displacement pump and by spraying the acid melt, at a rate of 1 gram/diaper, onto the
 15 absorbent airfelt wadding using two fan-shaped spray nozzles, one directed to the front of the diaper and one directed to the center. The spray rate of each nozzle is adjusted to around 90 grams/minute under a positive pressure of 10 to 20 psi (69 to 138 kPa).

The resulting disposable diaper is especially effective at maintaining the pH of urine discharged into the diaper at a value below 7.5. Diapers of substantively similar pH control effectiveness are provided when the
 20 molten adipic acid is applied to the topsheet, backsheet, airfelt, absorbent pad or onto a tissue insert by roller printing techniques well known in the art.

EXAMPLE V

A flexible substrate suitable for use as an antimicrobial agent-containing diaper insert is prepared by air-laying a web of cellulose fiber (airfelt) formed by disintegrating the CPC-impregnated drylap described in
 25 Example I. Such a web has dimensions of 10 inches (25.4 cm) X 4.5 inches (11.4 cm) X 0.20 inches (0.50 cm) and a density of 0.1 g/cm³.

The insert substrate thus contains 99% by weight airfelt and 1% by weight of the cetyl pyridinium
 30 chloride antimicrobial agent. The finished insert is prepared by wrapping this substrate in polypropylene diaper topsheet material (8 mils) and melt-bonding the overwrap at the ends.

An absorbent article of the present invention is prepared by positioning this insert substrate on top of the topsheet of a conventional absorbent gelling agent-containing diaper (e.g., ULTRA PAMPERS) which utilizes an absorbent core comprising particles of polyacrylate absorbent gelling buffering agent material
 35 admixed with airfelt. In such a configuration the polyacrylate absorbent gelling agent buffer comprises 1.2% by weight of the insert/diaper combination. Such an insert/diaper combination provides effective control of the pH of Proteus vulgaris-contaminated urine within the absorbent article.

Claims

- 40
1. A disposable absorbent article useful for absorbing urine and feces discharged by incontinent individuals while reducing or preventing diaper rash, said absorbent article comprising
 - (A) a liquid impervious backing sheet;
 - (B) a relatively hydrophobic, liquid pervious topsheet;
 - 45 (C) an absorbent core positioned between said backing sheet and said topsheet, said absorbent core comprising hydrophilic fiber material, and
 - (D) a pH control system;
 said absorbent article being characterized in that the pH control system consists essentially of
 - i) an acidic buffering agent formed by particles of a partially neutralised slightly cross-linked
 50 polymeric gelling agent having a degree of neutralisation of no more than 90%, and a gel volume of at least 20 grams of synthetic urine per gram of gelling agent, and
 - ii) an antimicrobial agent selected from quaternary nitrogen-based compounds and bisguanide compounds, said antimicrobial agent being combined with said absorbent core and present in or on
 said core in a concentration of from 0.02% to 2.0% by weight of the core,
 - 55 with said buffering agent component and said antimicrobial agent component, being present within said pH control system in a weight ratio of from 3:1 to 2000:1, with said pH control system being present in said absorbent article in an amount which is effective to maintain the pH of Proteus vulgaris-contaminated, bicarbonate-containing urine discharged into said article at a value below 7.5.

2. An article according to Claim 1 wherein the acidic buffering agent component is combined with the hydrophilic fiber material of the absorbent core and is present within said core in a concentration of from 2% to 50% by weight of the core.
- 5 3. An article according to either one of Claims 1 or 2 wherein the polymeric gelling agent buffer is selected from hydrolyzed acrylonitrile grafted starch, acrylic acid grafted starch, polyacrylates, maleic anhydride-based copolymers and combinations of these polymeric gelling agent buffers.
- 10 4. An article according to any one of Claims 1 to 3 wherein the polymeric gelling agent buffer has a gel volume of from 30 to 60 grams of synthetic urine per gram of gelling agent buffer and an equilibrium extractable polymer content in synthetic urine of no more than 17% by weight and is preferably a partially neutralised, slightly cross-linked sodium polyacrylate.
- 15 5. An article according to any one of Claims 1 to 4 wherein the hydrophilic fiber material of the absorbent core is selected from wood pulp fibers and stiffened, curled cellulosic fibers.
6. An article according to any one of Claims 1 to 5 wherein
 - (A) the antimicrobial agent is selected from methylbenzethonium chloride, benzalkonium chloride, dodecyltrimethyl ammonium bromide, tetradecyltrimethyl ammonium bromide, hexadecyltrimethyl ammonium bromide, dodecylpyridinium chloride, tetradecylpyridinium chloride, cetylpyridinium chloride, tetradecyl-4-ethylpyridinium chloride, tetradecyl-4-methylpyridinium chloride, chlorhexidine, the water-soluble salts of chlorhexidine and combinations of these antimicrobial agents; and
 - (B) the weight ratio of the acidic buffering agent component to the antimicrobial agent component ranges from 25:1 to 1000:1.
- 25 7. An article according to any one of Claims 1 to 6 wherein the absorbent core comprises an airlaid web of hydrophilic fibers having incorporated therein both the antimicrobial agent and particles of the polymeric gelling agent buffer, said web having a density of from 0.06 to 0.3 g/cm³.
- 30 8. An article according to any one of Claim 1 to 7 in the form of a diaper or incontinence brief wherein:
 - (A) the topsheet is coextensive with one face of said core;
 - (B) the backing sheet is coextensive with the face of the core opposite the face covered by said topsheet;
 - (C) both the topsheet and the backing sheet have a width greater than that of the core, to thereby provide side marginal portions of the topsheet and backing sheet which extend beyond the core; and
 - (D) the absorbent core is generally hourglass-shaped.
- 35 9. A diaper or incontinence brief according to Claim 8 wherein the antimicrobial agent is impregnated into the hydrophilic fibers forming the absorbent core and comprises from 0.05 to 1.0% by weight of said core or wherein the antimicrobial agent is intimately associated with the topsheet.
- 40 10. A diaper or incontinence brief according to Claim 8 wherein the antimicrobial agent is incorporated in or on a water-insoluble, flexible substrate positioned as an insert on top of the topsheet of the diaper or incontinence brief such that, when the diaper or incontinence brief is worn, the insert is next to the wearer's skin.
- 45

Patentansprüche

- 50 1. Ein wegwerfbarer absorbierender Artikel, der zur Aufnahme von Urin und Fäzes, die von inkontinenten Personen ausgeschieden werden, verwendbar ist und dabei Windelausschlag verringert oder verhindert, wobei der genannte absorbierende Artikel umfaßt:
 - (A) ein flüssigkeitsundurchlässiges Rückenblatt;
 - (B) ein relativ hydrophobes flüssigkeitsdurchlässiges Deckblatt;
 - (C) einen absorbierenden Kern, der zwischen dem genannten Rückenblatt und dem genannten Deckblatt angeordnet ist, wobei der genannte absorbierende Kern hydrophiles Fasermaterial umfaßt; und
 - (D) ein pH-Kontrollsystem;
- 55 wobei der genannte absorbierende Artikel dadurch gekennzeichnet ist, daß das pH-Kontrollsystem im

wesentlichen besteht aus

- i) einem sauren Puffermittel, das aus Partikeln einer teilweise neutralisierten schwach vernetzten polymeren gelbildenden Substanz mit einem Neutralisationsgrad von nicht mehr als 90 % und einem Gelvolumen von mindestens 20 g synthetischen Urins pro Gramm gelbildender Substanz gebildet ist, und
 - ii) einem antimikrobiellen Mittel, das aus quaternären Stickstoff-basierten Verbindungen und Bisguanid-Verbindungen ausgewählt ist, wobei das genannte antimikrobielle Mittel mit dem genannten absorbierenden Kern kombiniert ist und in oder auf dem genannten Kern in einer Konzentration von 0,02 Gew.-% bis 2,0 Gew.-% des Kerns vorliegt,
- wobei der aus dem genannten Puffermittel bestehende Bestandteil und der aus dem genannten antimikrobiellen Mittel bestehende Bestandteil innerhalb des genannten pH-Kontrollsystems in einem Gewichtsverhältnis von 3:1 bis 2000:1 vorliegen, wobei das genannte pH-Kontrollsystem im genannten absorbierenden Artikel in einer Menge vorliegt, welche wirksam ist, um den pH-Wert von mit Proteus vulgaris kontaminiertem, Bicarbonat enthaltendem Urin, der in den genannten Artikel abgegeben wurde, auf einem Wert unter 7,5 zu halten.
2. Ein Artikel nach Anspruch 1, in welchem der aus dem sauren Puffermittel bestehende Bestandteil mit dem hydrophilen Fasermaterial des absorbierenden Kerns kombiniert ist und innerhalb des genannten Kerns in einer Konzentration von 2 Gew.-% bis 50 Gew.-% des Kerns vorliegt.
 3. Ein Artikel nach einem der Ansprüche 1 und 2, in welchem der Puffer aus polymerer gelbildender Substanz ausgewählt ist aus hydrolysierte mit Acrylnitril gepfropfte Stärke, mit Acrylsäure gepfropfte Stärke, Polyacrylaten, Copolymeren auf der Basis von Maleinsäureanhydrid und Kombinationen dieser aus polymeren gelbildenden Substanzen bestehenden Puffer.
 4. Ein Artikel nach einem der Ansprüche 1 bis 3, in welchem der Puffer aus polymerer gelbildender Substanz ein Gelvolumen von 30 bis 60 Gramm synthetischen Urins pro Gramm des Puffers aus gelbildender Substanz und einen Gleichgewichtsgehalt von extrahierbarem Polymer in synthetischem Urin von nicht mehr als 17 Gew.-% aufweist und vorzugsweise ein teilweise neutralisiertes, schwach vernetztes Natrium-Polyacrylat ist.
 5. Ein Artikel nach einem der Ansprüche 1 bis 4, in welchem das hydrophile Fasermaterial des absorbierenden Kerns ausgewählt ist aus Holz-Zellstoff-Fasern und versteiften, gekräuselten Fasern auf Zellulose-Basis.
 6. Ein Artikel nach einem der Ansprüche 1 bis 5, in welchem
 - (A) das antimikrobielle Mittel ausgewählt ist aus Methylbenzethoniumchlorid, Benzalkoniumchlorid, Dodecyltrimethylammoniumbromid, Tetradecyltrimethylammoniumbromid, Hexadecyltrimethylammoniumbromid, Dodecylpyridiniumchlorid, Tetradecylpyridiniumchlorid, Cetylpyridiniumchlorid, Tetradecyl-4-ethylpyridiniumchlorid, Tetradecyl-4-methylpyridiniumchlorid, Chlorhexidin, den wasserlöslichen Salzen von Chlorhexidin und Kombinationen dieser antimikrobiellen Mittel; und
 - (B) das Gewichtsverhältnis des aus saurem Puffermittel bestehenden Bestandteils zu dem aus antimikrobiellem Mittel bestehenden Bestandteil im Bereich von 25:1 bis 1000:1 liegt.
 7. Ein Artikel nach einem der Ansprüche 1 bis 6, in welchem der absorbierende Kern eine im Luftstrom geschichtete Bahn aus hydrophilen Fasern umfaßt, in die sowohl das antimikrobielle Mittel als auch Partikel des Puffers aus polymerer gelbildender Substanz einverleibt sind, wobei die genannte Bahn eine Dichte von 0,06 bis 0,3 g/cm³ aufweist.
 8. Ein Artikel nach einem der Ansprüche 1 bis 7 in Form einer Windel oder Inkontinenzhose, in welchem
 - (A) sich das Deckblatt gemeinsam mit einer Seite des genannten Kerns erstreckt;
 - (B) sich das Rückenblatt gemeinsam mit jener Seite des Kerns erstreckt, die der von dem genannten Deckblatt bedeckten Seite gegenüberliegt;
 - (C) sowohl das Deckblatt als auch das Rückenblatt eine Breite aufweisen, die größer als die des Kerns ist, um auf diese Weise seitliche Randabschnitte des Deckblattes und des Rückenblattes zu ergeben, die sich über den Kern hinaus erstrecken; und
 - (D) der absorbierende Kern die allgemeine Form eines Stundenglases hat.

9. Une Windel oder Inkontinenzhose nach Anspruch 8, in welcher die den absorbierenden Kern bildenden hydrophilen Fasern mit dem antimikrobiellen Mittel imprägniert sind und dieses von 0,05 bis 1,0 Gew.-% des genannten Kerns ausmacht oder in welcher das antimikrobielle Mittel innig mit dem Deckblatt verbunden ist.

5

10. Eine Windel oder Inkontinenzhose nach Anspruch 8, in welcher das antimikrobielle Mittel in oder auf einem wasserunlöslichen flexiblen Substrat einverleibt ist, das als Einlage oben auf dem Deckblatt der Windel oder Inkontinenzhose angeordnet ist, sodaß, wenn die Windel oder Inkontinenzhose getragen wird, die Einlage der Haut des Trägers am nächsten liegt.

10

Revendications

1. Article absorbant jetable, utile pour absorber l'urine et les matières fécales, déchargées par des individus incontinents, tout en réduisant ou en empêchant l'efflorescence de la couche, ledit article absorbant comprenant :

15

- (A) une feuille de fond imperméable aux liquides ;
- (B) une feuille de dessus perméable aux liquides, relativement hydrophobe ;
- (C) une âme absorbante placée entre ladite feuille de fond et ladite feuille de dessus, ladite âme absorbante comprenant un matériau à fibres hydrophiles, et
- (D) un système d'ajustement du pH ; ledit article absorbant étant caractérisé en ce que le système d'ajustement du pH se compose essentiellement de

20

- i) un agent tampon acide formé par des particules d'un agent gélifiant polymère légèrement réticulé, partiellement neutralisé, ayant un degré de neutralisation qui n'est pas supérieur à 90%, et un volume de gel d'au moins 20 grammes d'urine synthétique par gramme d'agent gélifiant et
- ii) un agent antimicrobien choisi parmi les composés à base d'azote quaternaire et les composés bisguanide, ledit agent antimicrobien étant combiné avec ladite âme absorbante et présent dans ou sur ladite âme selon une concentration de 0,02% à 2,0% en poids de l'âme,

25

ledit agent tampon et ledit agent antimicrobien étant présents dans ledit système d'ajustement du pH selon un rapport pondéral de 3:1 à 2000:1, ledit système d'ajustement du pH étant présent dans ledit article absorbant selon une quantité qui est efficace pour maintenir à une valeur inférieure à 7,5, le pH d'une urine contenant du bicarbonate, contaminée par Proteus vulgaris, déchargée dans l'article

30

2. Article selon la revendication 1, dans lequel l'agent tampon acide est combiné à la matière à fibres hydrophiles de l'âme absorbante et est présent dans ladite âme selon une concentration de 2% à 50% en poids de l'âme.

35

3. Article selon l'une ou l'autre des revendications 1 et 2, dans lequel le tampon d'agent gélifiant polymère est choisi parmi l'amidon greffé d'acrylonitrile hydrolysé, l'amidon greffé d'acide acrylique, les polyacrylates, les copolymères à base d'anhydride maléique et les combinaisons de ces tampons d'agent gélifiant polymère.

40

4. Article selon l'une quelconque des revendications 1 à 3, dans lequel le tampon d'agent gélifiant polymère a un volume de gel de 30 à 60 grammes d'urine synthétique par gramme de tampon d'agent gélifiant et une teneur en polymère susceptible d'être extrait à l'équilibre, dans l'urine synthétique, ne dépassant pas 17% en poids et est de préférence un polyacrylate de sodium légèrement réticulé, partiellement neutralisé.

45

5. Article selon l'une quelconque des revendications 1 à 4, dans lequel la matière à fibres hydrophiles de l'âme absorbante est choisie parmi les fibres de pulpe de bois et les fibres celluloseuses ondulées rigidifiées.

50

6. Article selon l'une quelconque des revendications 1 à 5, dans lequel

- (A) l'agent antimicrobien est choisi parmi le chlorure de méthylbenzéthonium, le chlorure de benzalkonium, le bromure de dodécyl-triméthyl-ammonium, le bromure de tétradécyl-triméthyl-ammonium, le bromure de hexadécyl-triméthyl-ammonium, le chlorure de dodécylpyridinium, le chlorure de tétradécylpyridinium, le chlorure de cétylpyridinium, le chlorure de tétradécyl-4-éthylpyridinium, le chlorure de tétradécyl-4-méthylpyridinium, la chlorhexidine, les sels solubles dans l'eau de chlorhexidine et des combinaisons de ces agents antimicrobiens et

55

(B) le rapport pondéral de l'agent tampon acide à l'agent antimicrobien se situe dans la plage de 25:1 à 1000:1.

- 5 7. Article selon l'une quelconque des revendications 1 à 6, dans lequel l'âme absorbante comprend un feutre, formé par jet d'air, de fibres hydrophiles renfermant à la fois l'agent antimicrobien et les particules du tampon d'agent gélifiant polymère, ledit feutre ayant une masse volumique de 0,06 à 0,3 g/cm³.
- 10 8. Article selon l'une quelconque des revendications 1 à 7 sous la forme d'une couche ou d'une culotte pour incontinent, dans lequel :
 - (A) la feuille de dessus s'étend sur toute la longueur d'une face de ladite âme ;
 - (B) la feuille de fond s'étend sur toute la longueur de la face de l'âme, opposée à la face couverte par ladite feuille de dessus ;
 - 15 (C) tant la feuille de dessus que la feuille de fond ont une largeur supérieure à celle de l'âme, afin de définir des parties de lisière latérale de la feuille de dessus et de la feuille de fond, qui s'étendent au-delà de l'âme ; et
 - (D) l'âme absorbante a la forme générale d'un sablier.
- 20 9. Couche ou culotte pour incontinent selon la revendication 8, dans laquelle l'agent antimicrobien est incorporé par imprégnation dans les fibres hydrophiles formant l'âme absorbante et représente de 0,05 à 1,0% en poids de ladite âme, ou dans laquelle l'agent antimicrobien est lié intimement à la feuille de dessus.
- 25 10. Couche ou culotte pour incontinent selon la revendication 8, dans laquelle l'agent antimicrobien est incorporé dans ou sur un substrat souple insoluble dans l'eau, placé, sous forme d'un élément rapporté, sur le dessus de la feuille de dessus de la couche ou de la culotte pour incontinent, de sorte que, lorsque la couche ou la culotte pour incontinent est portée, l'élément rapporté est au voisinage de la peau de l'utilisateur.
